OCEAN TIDES

noise ilde and Abbiert

Introductory Oceanography RayRector: Instructor

Tidal Concepts

- Tides are extremely swift, very long-wavelength, shallow-water waves
- Tides are periodic short-term changes in sea level at a particular place caused by the gravitational force of the moon and sun, and the motion of the Earth
- > The moon's influence is twice as great as that of the sun's
- Gravity's attractive force and inertia's flinging-away force combine to produce two ocean tidal bulges
- The Earth rotating underneath the tidal bulges causes tides
- The equilibrium theory of tides only takes into account gravitational and rotational affects under equilibrium conditions without regard to ocean basin shape, water depth, ocean inertia, Coriolis effect, nor sea bottom friction drag
- The dynamic theory of tides is a much more robust prediction model that also takes account all those factors left out of the equilibrium theory (listed above)
- Tidal patterns take three forms worldwide: diurnal, semidiurnal, and mixed
- Tides in each ocean basin form a rocking-rotary cycle around *amphidromic* "no tide" points – counterclockwise in N. Hemi, clockwise in the S. Hemi

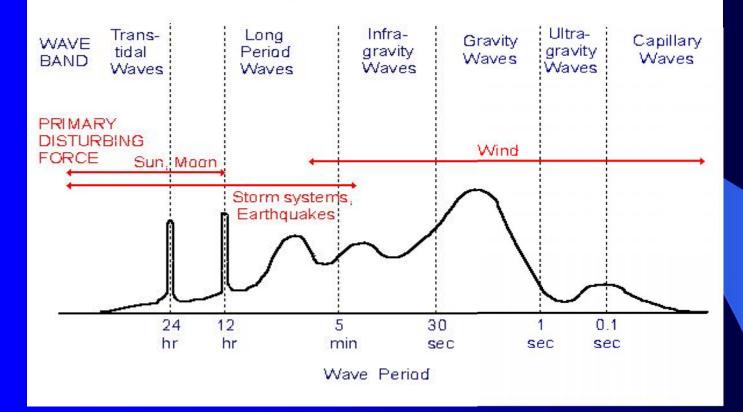

Time-lapse Video of Bay of Fundy Tides

Ocean Wave Energy

QUALITATIVE WAVE POWER SPECTRUM

Schematic guestimation of the energy (power spectrum) contained in the surface waves of the ocean

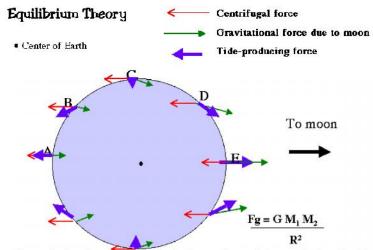

Reference: Kinsman, Blair, <u>Wind Waves: Their Generation and Propagation on the Ocean</u> <u>Surface</u>. Prentice-Hall, Inc., Englewood Cliffs, New Jersey, 1965, p. 23.

Equilibrium Theory of Tides

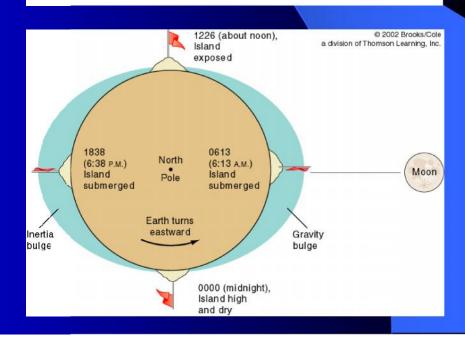

<u>Concepts</u>

Equilibrium theory of tides combines the fundamentals of Newtonian celestial gravity and inertia mechanics and a rotating Earth to predict the tides

- Equilibrium theory assumes that
 - Ocean surface is at equilibrium with forces acting upon it
 - ✓ Idealized bottomless ocean column
 - No landmass obstructions
 - ✓ No Coriolis effect
- Equilibrium theory of tides predicts
 - ✓ Two tidal bulges
 - Two highs and low tides per day
 - Tidal amplitudes of less than 1 meter
- Equilibrium theory fails to predict:
 - ✓ Two-meter plus tides
 - Diurnal and mixed tide patterns
 - Slow tidal wave velocities
 - Amphidromic rotary tide movements

The tide producing force at any point is the resultant of the gravitational and centrifugal forces at that point and varies inversely with the cube of the distance from the moon. *How is that possible with* \mathbb{R}^2 ?

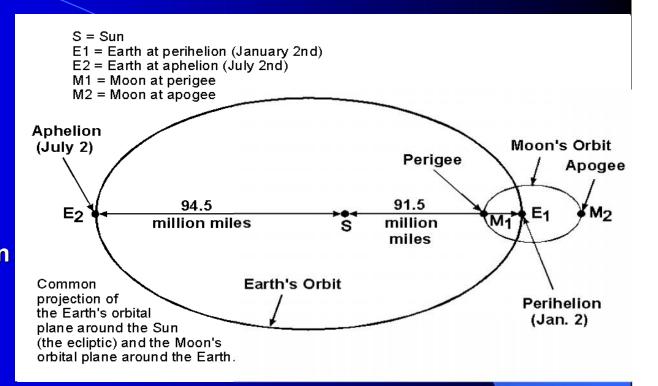

Earth – Moon – Sun Relationship

<u>Earth's Orbit</u>

Perihelion
Closest to Sun
January 2nd
Japhelion
Farthest from Sun
July 2nd

<u>Moon's Orbit</u>

- Perigee
 - ✓ Closest to Earth
 - ✓ Twice a month
- Apogee
 - ✓ Furthest from Earth
 - ✓ Twice a month

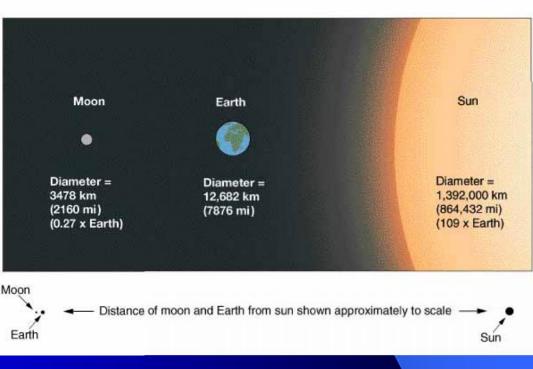

Earth – Moon – Sun Relationship

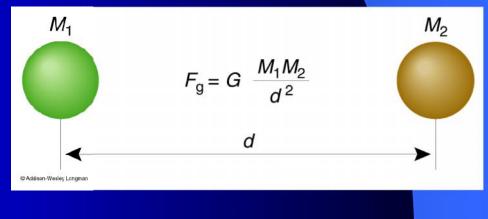

<u>Mass vs. Distance</u>

- Sun is 27 million times more massive than Moon
- Earth is 81 times more massive than the Moon
- The Sun is 387 times farther away from Earth than the moon
- Solar tidal effect is only 46% that of the moon

Gravitational Relationship

- **m1** = gravitational pull of 1st planet
- **m2** = gravitational pull of 2nd planet
- **d** = distance between the planets
- **G** = gravitational constant

Revolving Earth- Moon System

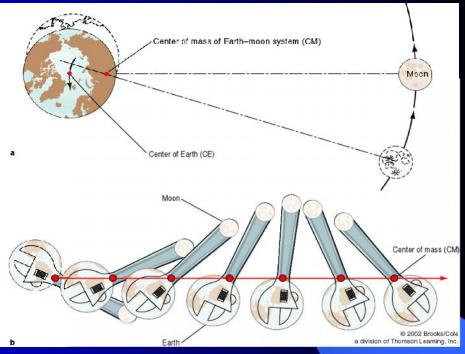

Moon and Earth revolve around a mutual center of mass

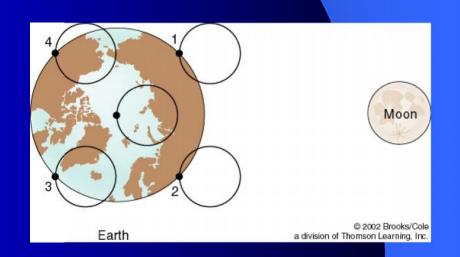

Revolution cycle = 29.5 days

Common center of mass is located 1,650 kilometers beneath the Earth's surface

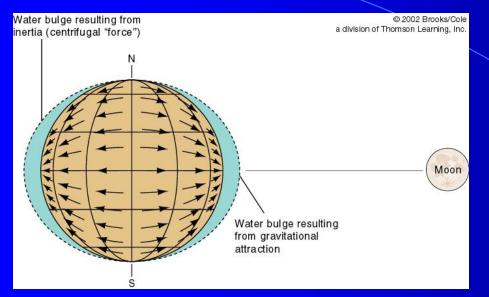

A perfect balance between gravitational attraction and inertial repulsion keeps the two bodies in stable orbit around one another

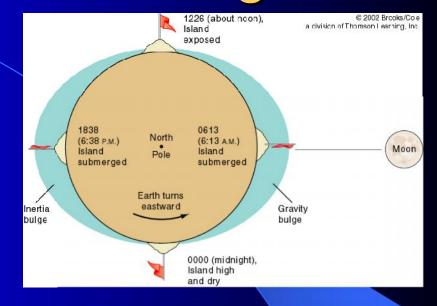

Gravity, inertia, and a rotating Earth, are the root causes of tides

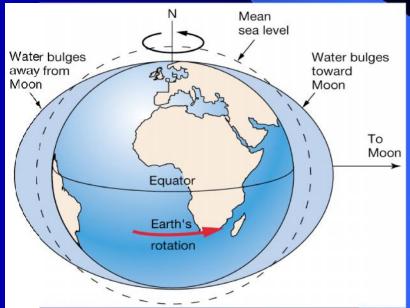

Earth's Twin Tidal Bulges

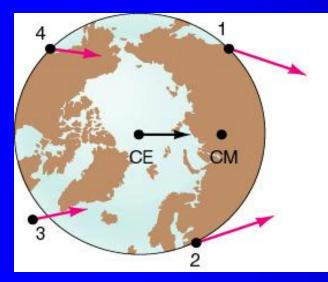

Earth has two tidal bulges:
1) Inertia bulge
2) Gravity bulge
Tidal bulges move west to east due to Earth's rotation

Tide-Generating Forces

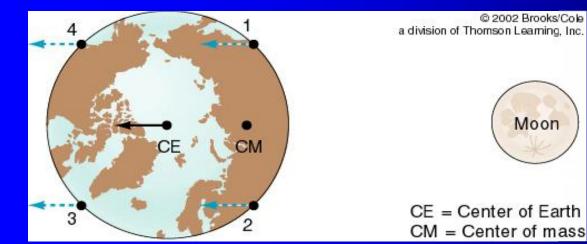

© 2002 Brooks/Cole a division of Thomson Learning, Inc.

CE = Center of Earth CM = Center of mass Gravity (pulling-toward force)

- ✓ Attractive force
- Unequally distributed
- ✓ Unequally directed
- ✓ Strongest nearest moon

Inertia (flinging-away force)

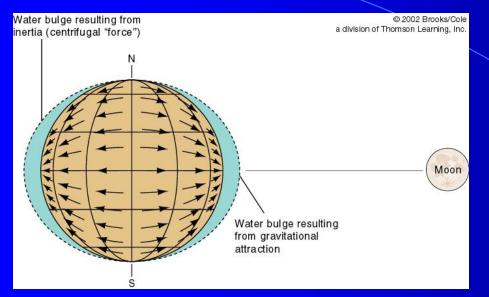

- ✓ Centrifugal effect
- ✓ Repelling force
- Equally distributed
- ✓ Equally directed

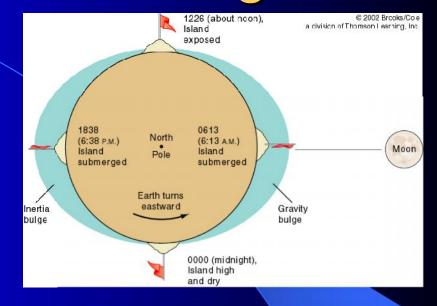

Interaction of the Tidal Forces © 2002 Brooks/Cole Inertia (sometimes called centrifugal "force"): a division of Thomson Learning, Inc. The same for all particles in and on Earth. Gravitational attraction: Decreases as the square Bulge of the distance from the moon. At the center of opposite Earth (CE), the gravitational force is precisely moon equal in strength but opposite in direction to inertia. CE Moon Bulge toward moon Forces are balanced here Tractive forces: Create two bulges in the ocean, one in the direction of the moon, the other opposite.

The two forces that can move the ocean are balanced only at the center of Earth (point CE). Elsewhere the net imbalance is a small force that causes ocean water to converge into two equal "bulges," as shown.

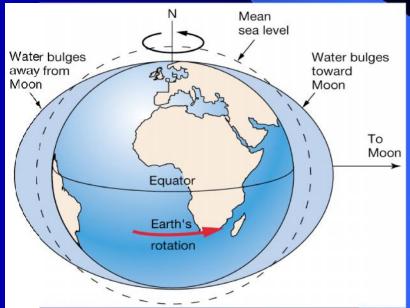

The combined forces of gravitational attraction and inertia create a net balanced force called "tractive forces"

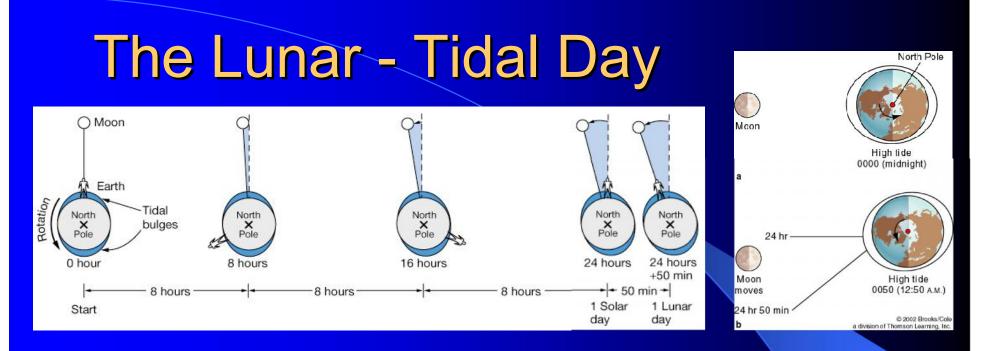

Earth's Twin Tidal Bulges

Earth has two tidal bulges:
1) Inertia bulge
2) Gravity bulge
Tidal bulges move west to east due to Earth's rotation

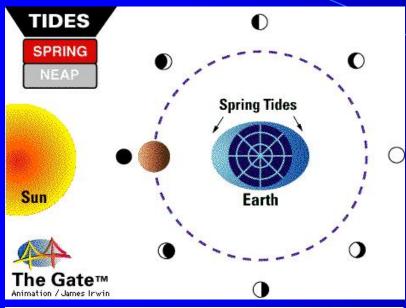

Solar Earth Day - Earth completes one rotation relative to the sun in 24 hours

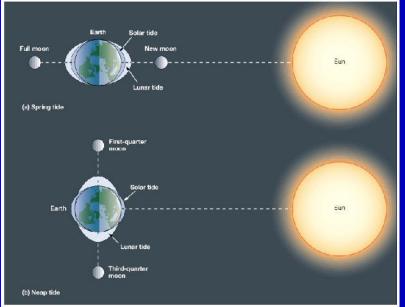

Lunar Earth Day - Earth completes one rotation relative to the moon in 24 hours 50 minutes

Earth – Moon System completes one revolution in 29.5 days (one lunar month/cycle) or 1/12 of a revolution in one solar Earth day

- One Lunar Tidal Cycle = 24 hours 50 minutes
- Arrival of a new tide cycle occurs 50 minutes later each day

Spring Tide Versus Neap Tide

Spring Tide

- Gravitational pull of the sun and moon are in line with each other
- Daily tidal variations on Earth are at their greatest
- Occur during new and full moon phases

Neap Tide

- Gravitational pull of the sun and moon are at right angles to each other
- Daily tidal variations on Earth are at their least
- Occur during first and last quarter of the moon

The Dynamic Theory of Tides

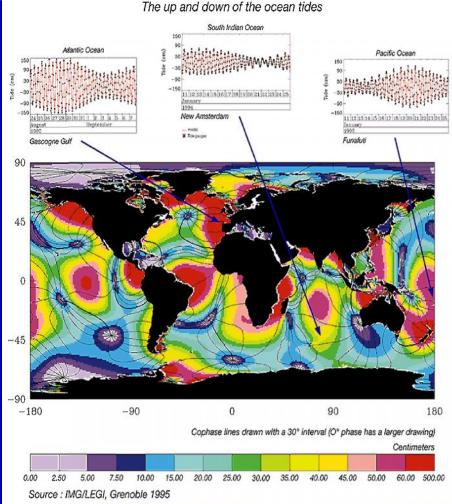

<u>Concepts</u>

Dynamic theory of tides combines the fundamentals of the equilibrium theory with several major fluid motion problems related to:

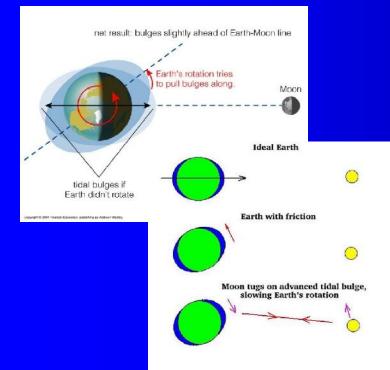

- Landmass obstructions
- ✓ Ocean basin shape
- Friction drag of sea bottom
- Shallow-water wave behavior
- ✓ Coriolis effect
- Inertia of water column

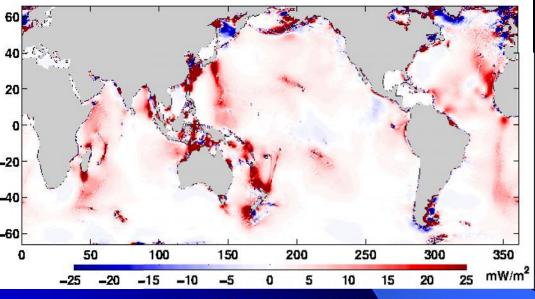

Dynamic theory of tides explains the differences between predictions based on Newton's equilibrium model and the actual observed behaviors of tides

Actual tidal movement is modeled as a basin-scale set of interconnected amphidromic rotary wave circuits

Tidal Bulges and Sea Bottom Drag

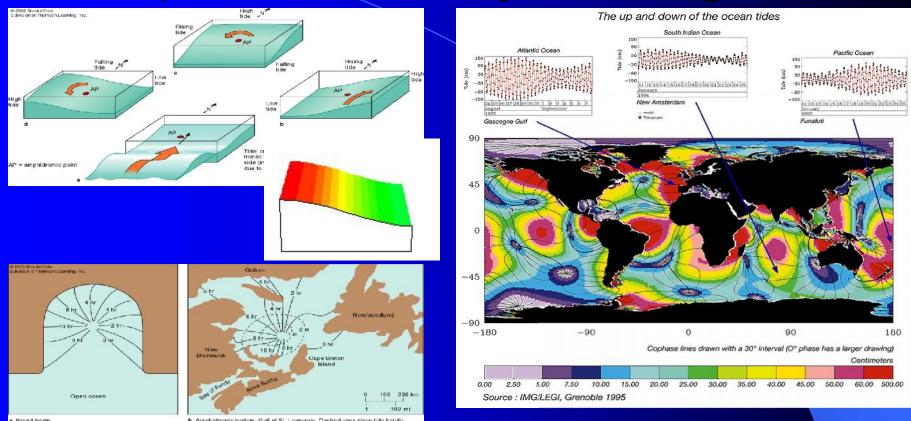

Regions of Greatest Tidal Drag

Earth rotates beneath tidal bulge

Frictional drag between ocean column and sea bottom pulls tidal bulge eastward of Earth-moon centerline

Ocean water column inertia also causes tidal bulge to lag behind the predicted "equilibrium model" bulge

Amphidromic Rotary Standing Waves

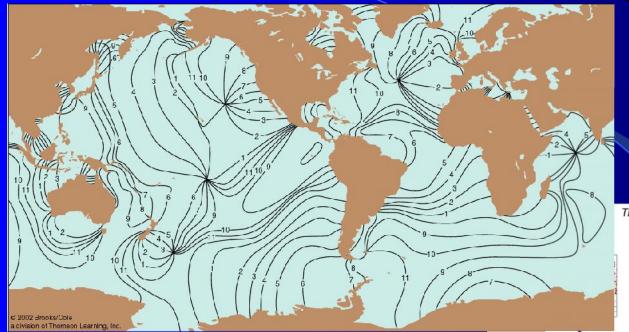

Coriolis effect plays major part in causing rotary tide motion

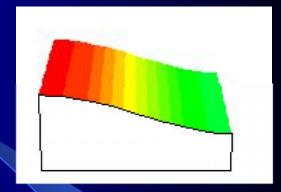

Centerpoint of the tide's rotational standing wave is termed the "amphidromic node" where zero tides occur

Tide amplitude increases with distance from node points

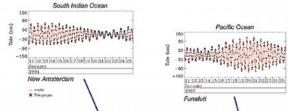

Counterclockwise rotation in the N. Hemi – clockwise rotation in S. Hemi

Amphidromic Tidal Systems

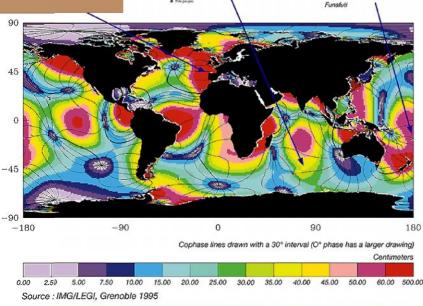

The up and down of the ocean tides

Tide amplitude varies with distance from node points

- Zero tide at node points
- Overlapping of amphidromic systems

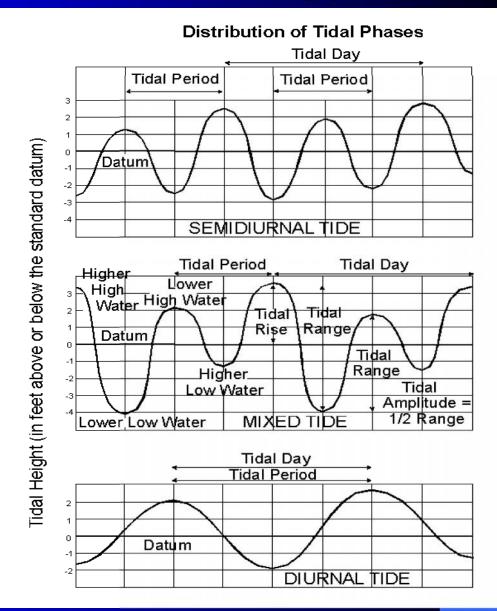

Pacific basin most complicated

Ocean Tide Terminology

Important Terms

- Mean Sea Level
- Tidal datum
- Tidal day
- ➤ Tidal period
- Tidal range
- Tidal amplitude
- ➤ Tidal phases
- Neap and spring tide
- Higher high water
- High water
- Low water
- Lower low water
- Ebb, slack, and flood

Three Patterns of Ocean Tides

1) Semidiurnal Tide

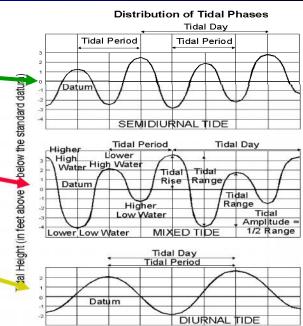

- Two highs, two lows
- ✓ Highs and lows similar
- ✓ Atlantic and Arctic Oceans

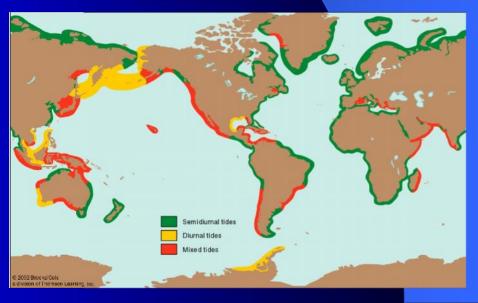

2) Mixed Tide

- ✓ Two highs, two lows
- ✓ Highs and lows dissimilar
- Pacific and Indian Oceans

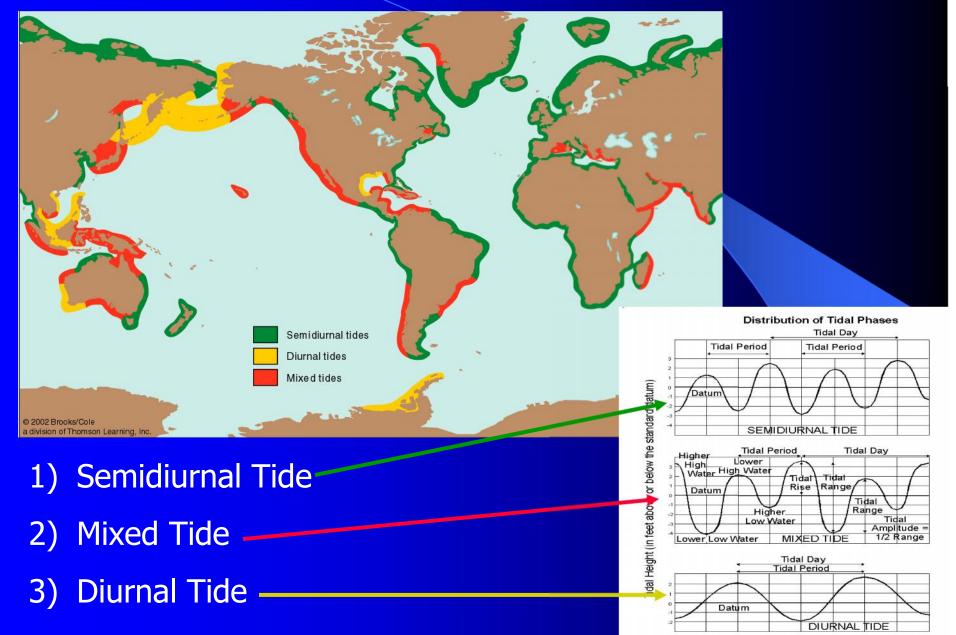

3) Diurnal Tide

- ✓ One high, one low
- Aleutians, Indonesia and Gulf of Mexico

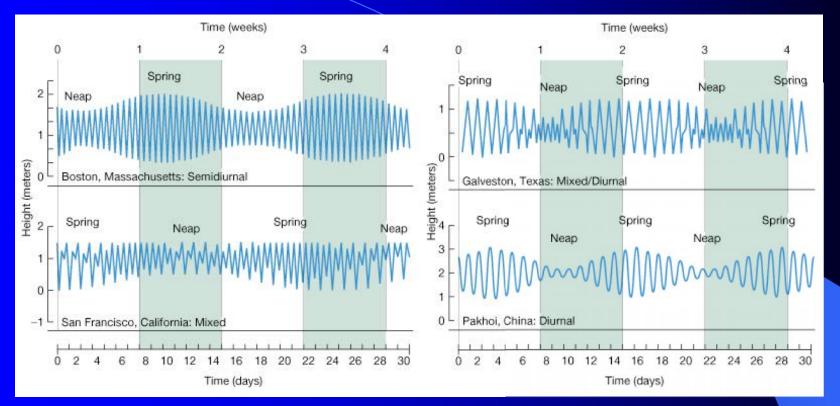

Three Patterns of Ocean Tides

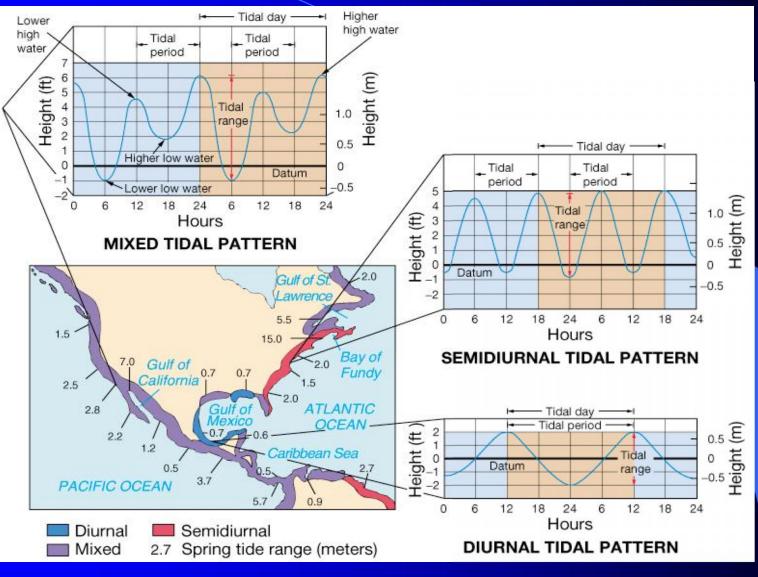

Monthly Tidal Cycles

Boston, Mass. - Semidiurnal Galvelston, Texas – Diurnal San Francisco, CA - Mixed Pakhoi, China - Diurnal

Tidal Patterns of North America

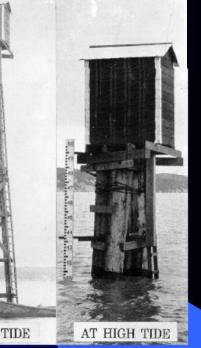

Measuring Tidal Changes

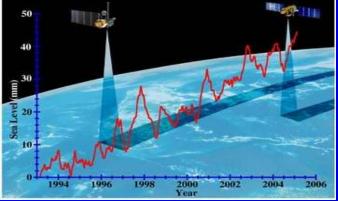

<u>Methods</u>

- 1) Tidal Staffs
- 2) Tidal Gauges
 - 🗸 Float levels
 - ✓ Gas-purged bubblers
 - ✓ Ultrasonic altimeters
- 3) Bottom pressure sensors
- 4) Satellite altimetry

Modern methods

Old-style

2000

2100

Tidal Datum

A tidal datum is a base elevation in which to reckon heights and depths in terms of a phase of tide

Tidal datums are based on a phase of the tide

MHW = mean high water

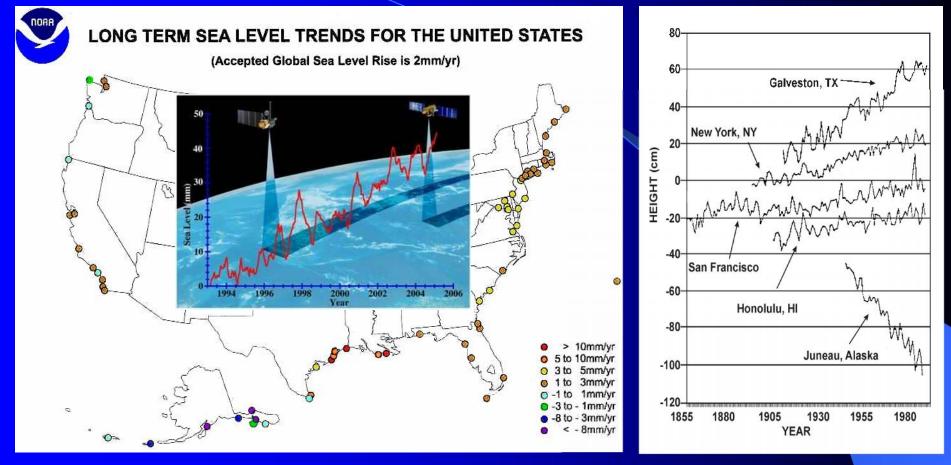

MLLW = mean low low water

Tide station datums are based on a 19 year mean called an National Tidal Datum Epoch (NTDE).

Tide stations are referenced to a bench mark system for stability checks & long term maintenance.

 Datum applications: Ports, chart depths, marine boundaries, hydrographic surveys, dredging, storm surge, modeling, wetland restoration, etc.

Sea Level Changes Around the USA

Questions:

- 1) How does changing sea level affect coastal areas over time?
- 2) How does changes in sea level affect tidal datum and tide prediction?

32.8667° N, 117.2567° W

Questions:

- What is the tidal datum for this chart?
- 2) What is the MLLW?
- 3) How low are the minus tides?
- 4) When do the four Lunar phases occur in the month?

Applications of Tide Prediction

COASTA

AND MANAGEMENT

PI ANNI

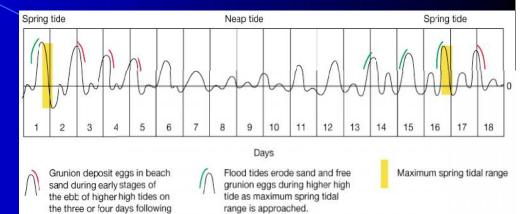

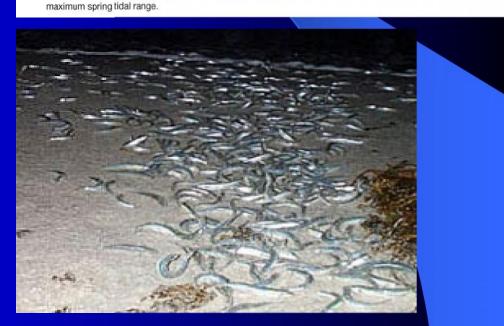

Grunion and the Tides

Grunion Facts:

- Grunion are the only fish that come completely out of water to spawn
- Spawning cycles are timed precisely with the tides
- Grunion leave the water at night to spawn on the beach in the spring and summer months two to six nights after the full and new moons
- Spawning begins after high tide and continues for several hours.
